Discription:

IGF Des1-3 is an important member of insulin-like growth factor, which is highly homologous with insulin-like growth factor. Other members of the system include IGF , 1gf-I receptor (IGFIR), IGF receptor (IGFIIR) and four insulin growth factor binding proteins (IGFBP-1, - 2, - 3, - 4).

Insulin like growth factor-1 (IGF-1) is a single chain basic polypeptide composed of 70 amino acids with a molecular weight of 7649. It comes from many cells in vivo and plays a variety of physiological roles by combining with IGF-1 receptor (IGF-1R) through autocrine, paracrine and endocrine mechanisms.

It is a factor that promotes cell growth and has insulin-like metabolism. IGF-1 is regulated by nutritional status, hormones, genetics and other factors. It plays an Vital role in the pathophysiology of cardiovascular diseases, endocrine and metabolic diseases and tumors.

Function:

- (1) Helps regulate fat for use as energy, resulting in fat loss.
- (2). Contributes to anti aging. As we get older, GF-1 production slows down and this results in cell reduction. Low levels of GF-1 are linked to heart failure, lower brain cell regulation and neuron function. Not to mention muscle tissue breakdown.
- (3). Helps to increase nutrient shuttling (protein synthesis).
- (4). Increases regenerative functions of nerve tissues.
- (5). Boosts the ability to cause hyperplasia in muscle cells resulting in fuller muscle
