Brief Introduction of gh frag 176-191

GH fragment 176-191 is a fragment molecule of gh, which consists of 16 amino acid growth hormones (amino acids at positions 176-191 at the C-terminus of the gh. This peptide fragment stimulates lipolysis and suppresses the formation of new fat mass.

GH Fragment 176-191 is a small, synthetic piece of natural GH. It is often referred to as the "lipolytic fragment" for its ability to boost fat loss. It has been shown to help lowers blood sugar levels and promote cartilage healing without increasing long bone growth, increasing IGF-1 levels, or altering insulin sensitivity.

Fragment 176-191 (modified version of AOD9604) is a small piece of GH that is sometimes referred to as the "lipolytic fragment." Fragment 176-191 earned this latter name due to the fact that laboratory research has shown it to enhance fat burning, particularly in mice genetically engineered to produce large fat stores. Fragment 176-191 has been heavily researched in animal models because even while it preserves the fat-burning effects of GH, it avoids some other effects of its parent protein such as increasing insulin-like growth factor-1 (IGF-1) levels, negatively impacting carbohydrate metabolism, altering insulin sensitivity, increasing long bone growth, and so forth. The targeted effects of fragment 176-191 make it useful for exploring human fat metabolism and may eventually provide the basis for developing anti-obesity medications.
