Brief Introduction of Tesamorelin

Tesamorelin is a synthetic peptide consisting of all 44 amino acids of hGRF with the addition of a trans-3-Hexenoic acid group and a synthetic form which is used in the treatment of HIV-associated lipodystrophy.

Tesamorelin has been shown to reduce lipodystrophy in HIV-infected individuals. Lipodystrophy is a condition that causes changes in placement of body fat, including wasting and fat accumulation, and changes in metabolism.

Tesamorelin, (formerly known as TH9507), is a type of peptide called a growth hormone-releasing factor (GHRF). GHRF causes growth hormone to be created and spread in the body, which helps increase metabolism, reduce belly fat, improve body shape, and use of energy.

Tesamorelin (formerly known as TH9507) is a synthetic growth hormone-releasing factor that stimulates the pituitary gland in the brain to secrete growth hormone; this indirect approach appears to maintain more stable, natural levels, like CJC-1295 DAC,. Clinical trials have shown that tesamorelin significantly reduces abdominal fat with fewer side effects than human growth hormone itself, although abdominal fat may return after the Tesamorelin is discontinued (depending upon the individual). Tesamorelin has been shown to reduce lipodystrophy in HIV-infected individuals as well as similarly reducing abdominal fat in NON-HIV-Infected individuals.

This medication is a synthetic GHRF. It stimulates the production of growth hormones by binding to receptors on anterior pituitary cells. These growth hormones affect metabolism and body shape. Tesamorelin targets fat accumulation in the abdominal area specifically. As this drug releases growth hormones, patients with active cancer should not take it.
